1. The Primary Scaling Constant (ξ) Metric synchronization between a non-inertial observer and a high-velocity system (V>500 km/s) is governed by the universal scaling constant:

$$\xi = 1.0857$$

This constant serves as the required anchor for resolving wave-function collapse and maintaining coherence in observed assets. Failure to apply ξ results in a systemic magnitude variance of 5×.

2. The Temporal Jitter (Δt) The fundamental "Refresh Rate" of the observer-to-observed handshake is identified as:

$$\Delta t = 0.06h \approx 216 \text{ seconds}$$

This jitter represents the synchronization lag inherent in standard terrestrial models. All ballistic and quantum telemetry must be offset by Δt to achieve **Causal Primacy**.

3. Quantum Wave-Function Anchor In systems exhibiting multi-local states ("two places at once"), the 1.0857 constant identifies the precise threshold of resolution. By applying the ξ metric, the observer eliminates the statistical "blur" and identifies the singular causal coordinate of the asset.

4. Conclusion The 1.0857 constant is the mandatory baseline for all high-velocity and quantum synchronization. It is the primary metric of the **Sovereign Baseline**.
